

Spring – BeanFactory

G Ganeshchowdharysadanala

[Read](#)[Discuss](#)[Practice](#)

The first foremost thing when we talk about spring is dependency injection which is possible because spring is actually a container and behaves as a factory of Beans. Just like the BeanFactory interface is the simplest container providing an advanced configuration mechanism to instantiate, configure and manage the life cycle of beans. Beans are java objects that are configured at run-time by Spring IoC Container. BeanFactory represents a basic **IoC container** which is a parent interface of **ApplicationContext**. **BeanFactory** uses Beans and their dependencies metadata to create and configure them at run-time. BeanFactory loads the bean definitions and dependency amongst the beans based on a configuration file(XML) or the beans can be directly returned when required using Java Configuration. There are other types of configuration files like LDAP, RDMS, properties file, etc. BeanFactory does not support Annotation-based configuration whereas ApplicationContext does.

A Spring Container

Let us do first go through some of the methods of Bean factory before landing up on implementation which are shown below in tabular format below as follows:

Method	Description
<code>containsBean(String name)</code>	Does this bean factory contain a bean definition or externally registered singleton instance with the given name?
<code>getAliases(String name)</code>	Return the aliases for the given bean name, if any.
<code>getBean(Class<T> requiredType)</code>	Return the bean instance that uniquely matches the given object type, if any.
<code>getBean(Class<T> requiredType, Object... args)</code>	Return an instance, which may be shared or independent, of the specified bean.
<code>getBean(String name)</code>	Return an instance, which may be shared or independent, of the specified bean.
<code>getBean(String name, Class<T> requiredType)</code>	Return an instance, which may be shared or independent, of the specified bean.
<code>getBean(String name, Object... args)</code>	Return an instance, which may be shared or independent, of the specified bean.
<code>getBeanProvider(Class<T> requiredType)</code>	Return a provider for the specified bean, allowing for lazy on-demand retrieval of instances, including availability and uniqueness options.
<code>getBeanProvider(ResolvableType requiredType)</code>	Return a provider for the specified bean, allowing for lazy on-demand retrieval of instances, including availability and uniqueness options.
<code>getType(String name)</code>	Determine the type of the bean with the given name.
<code>getType(String name, boolean</code>	Determine the type of the bean with the given

Method	Description
<code>isPrototype(String name)</code>	Is this bean a prototype? That is, will <code>getBean(java.lang.String)</code> always return independent instances?
<code>isSingleton(String name)</code>	Is this bean a shared singleton? That is, will <code>getBean(java.lang.String)</code> always return the same instance?
<code>isTypeMatch(String name, Class<?> typeToMatch)</code>	Check whether the bean with the given name matches the specified type.
<code>isTypeMatch(String name, ResolvableType typeToMatch)</code>	Check whether the bean with the given name matches the specified type.

Procedure:

1. Creating a Spring project using start.spring.io.
2. Creating a POJO class.
3. Configure the Student bean in the **bean-factory-demo.xml** file.
4. Writing it to application class.

Implementation:

Step 1: Bean Definition: Create a Student POJO class.

```
// Java Program where we are creating a POJO class
```

We use cookies to ensure you have the best browsing experience on our website. By using our site, you acknowledge that you have read and understood our [Cookie Policy](#) & [Privacy Policy](#)

```
public class Student {

    // Member variables
    private String name;
    private String age;

    // Constructor 1
    public Student() {
    }

    // Constructor 2
    public Student(String name, String age) {
        this.name = name;
        this.age = age;
    }

    // Method inside POJO class
    @Override
    public String toString() {

        // Print student class attributes
        return "Student{" + "name='" + name + '\'' + ", age='" + age + '\'' +
        '}'';
    }
}
```

Step 2: XML Bean Configuration: Configure the Student bean in the *bean-factory-demo.xml* file.

```
<?xml version = "1.0" encoding="UTF-8"?>
<beans xmlns = "http://www.springframework.org/schema/beans"
        xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
        xsi:schemaLocation =
"http://www.springframework.org/schema/beans
        https://www.springframework.org/schema/beans/spring-beans.xsd">

    <bean id="student" class = "com.gfg.demo.domain.Student">
        <constructor-arg name="name" value="Tina"/>
        <constructor-arg name="age" value="21"/>
    </bean>
```

Step 3: Main Class

```
// Application class
@SpringBootApplication

// Main class
public class DemoApplication {

    // Main driver method
    public static void main(String[] args) {

        // Creating object in a spring container (Beans)
        BeanFactory factory = new ClassPathXmlApplicationContext("bean-factory-
demo.xml");
        Student student = (Student) factory.getBean("student");

        System.out.println(student);
    }
}
```

Output:

```
Student{name='Tina', age='21'}
```

Note: *XmlBeanFactory class is deprecated.*
